MILK COWS, ALSO HEIFERS AND CALVES BEING KEPT FOR MILK COWS NUMBERS ON FARMS JANUARY 1, 1920-41

(WITH SUPPLEMENTARY ESTIMATES OF MILK COWS, JUNE 1,1930-40)

U. S. DEPARTMENT OF AGRICULTURE

NEG. 356 AGRICULTURAL MARKETING SERVICE

The number of milk cows has turned sharply upward in recent months. The number has now started to rise above average in proportion to the population, and a record number of heifers will be added to milking herds this year. The number of heifer calves being kept for milk cows also appears abnormally high. Some of the causes and effects of these changes are explained on page 10.

The production of milk and dairy products climbed into new ground in January, the Agricultural Marketing Service reports. Compared with output in January last year, the estimates show these outstanding increases—milk 5.7 percent, creamery butter 7.7, American cheese 15.9, and principal manufactured dairy products together, nearly 9 percent

January milk production is estimated at 8,416 million pounds. This is between 12 and 13 percent above the 5-year average for January and even higher than the average for March. The heavy production was shared by practically all parts of the country and it apparently resulted chiefly from an increased number of cows, extra-liberal feeding and continued mild weather. Compared with January last year, the number of milk cows was up about 2 percent, the quantity of concentrates fed per cow was probably up at least 2 percent and January temperatures in producing areas averaged 3 to 4 degrees above normal in contrast to about 7 degrees below normal last year.

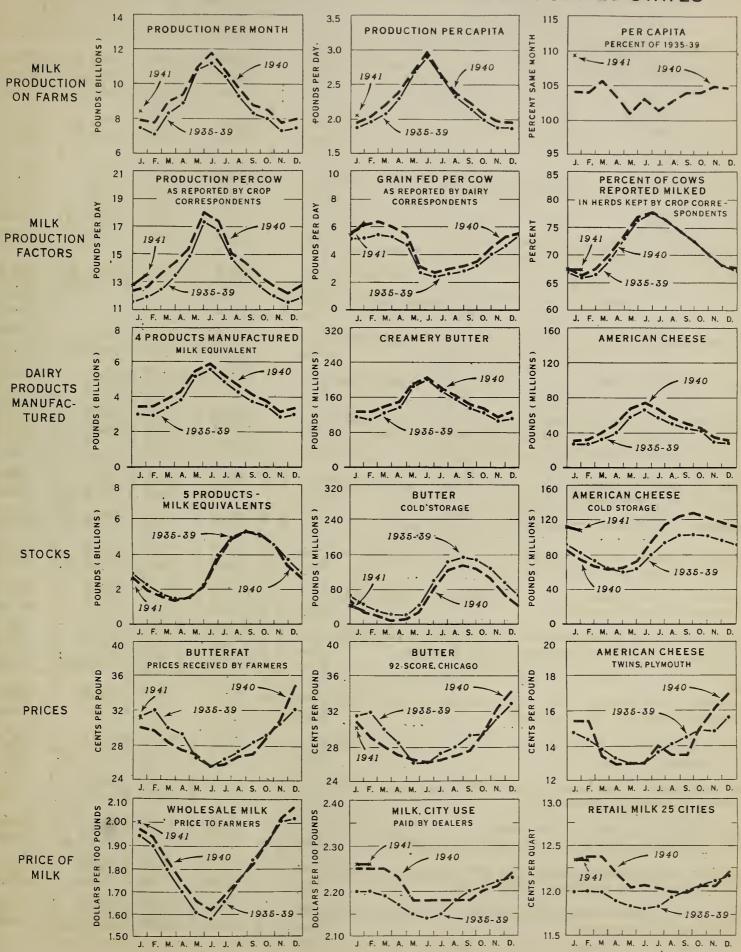

Production as much above normal for the season as occurred in January has seldom continued long, partially because conditions favorable for heavy feeding have soon been undermined by increases in supplies of dairy products in storage. Production in January was so heavy that the movement of dairy products out of storage was only a little more than half the average volume. Commercial stocks of dairy products, which were about 7 percent above the 5-year average on January 1, were about 26 percent above average on February 1. Holdings of cheese are particularly heavy.

Due in part to government purchases of butter, prices of principal dairy products have held fairly steady during the past month except for the 1 cent drop in cheese. Prices are mostly close to the 5-year averages for this season of the year. In mid-February prices being received for milk and butterfat appear about as favorable in comparison with the combined value of hay, grain and feed-stuffs as at the same season in any of the past 5 years. However, the recent sharp increases in the prices of cattle, hogs and sheep, if maintained, will tend to lessen the pressure to expand dairy herds.

CRAIN FED PER MILK COW: On February 1 dairy correspondents were feeding their cows less than 1 percent more grain and concentrates per head than at the same time last year but from 5 to 44 percent more than on the same date in other years since 1931, when the records were started. Crop correspondents, a larger group and more representative of average producers, were feeding 2.6 percent more than a year ago and only a fraction of 1 percent fewer pounds than in February 1932 when they were feeding freely with 20-cent corn, but feeding much of it without grinding. In February this year they were feeding a better balanced ration and probably a better quality of hay than in 1932 and they were obtaining 6 percent more milk per pound of concentrates fed.

Reports from crop correspondents in New York, Pennsylvania, Michigan, Missouri, Morth Dakota, and a few scattered States in other parts of the country, showed rates of feeding on February 1 as high or higher than on that date in any of the past 9 years for which records are available. On the other hand, in a number of Corn Belt and Southwestern States the rate of feeding was lower than in some of the depression years, and in Ohio and Indiana, where drought last summer reduced feed production, the rate of feeding was below the average for February 1, as shown by the table on page 5.

1/ 1) mires	tor New Englar	מרומול מו	are besed or	n anmorned returns	irom crop	and special	darry re-

Figures for New England Species are based on combined returns from crop and special dairy reporters (milk per cow weighted by counties). Figures for other States, regions, and U.S. are based on returns from crop reporters only. The regional averages are based in part on records of less important dairy States not shown separately, as follows: North Atlantic, Rhode Island; South Atlantic, Delaware and Florida; South Central, Alabama and Louisiana; Western, New Mexico, Arizona, Utah, and Nevada.

2 Averages per cow computed from answers to question, "How many pounds of grain (including mill feeds and concentrates) were fed yesterday to milk cows on your farm (or ranch)?"

3 Averages represent the reported daily milk production of herds kept by reporters divided by the total number of milk cows (in milk or dry) in these herds.

cdm

ANNUAL MILK PRODUCTION IN 1940

Milk production on farms in 1940, estimated at 111.1 billion pounds, exceeded that in 1939 by 2.3 percent and represents a record high per capita production in the 17-year period for which records are available. Milk production per cow, favored by the third best pasture season of the decade and by liberal feeding of abundant grain and concentrate supplies, was well above average in all months, and for the year averaged 4,575 pounds or 532 gallons, less than 1 gallon per cow below the 1929 record. The average number of milk cows on farms during the year, estimated at 24.3 million head was the largest since 1935, but still was some 4 percent short of the record number of 1934. The 1939 and 1940 estimates for the various States as given on page 7 show that, outside of the Cotton Belt, increases in the number of milk cows, in production per cow, and in total milk production were rather general, the chief exceptions being scattered states where crops and pastures suffered from drought or where interest has shifted to beef cattle. Increases in production were substantial in some of the States recovering from former droughts and were around 6 or 7 percent in a number of the intensive dairy States, including Vermont, New York, Wisconsin and Idaho. In the South milk production increased in the dairy area extending from Virginia northeastward and appears to have been maintained in Texas but in most other States production was lower in 1940 than in 1939. Most of the decreases in the South appear to have been due to the severe winter, poor pastures and local shortages of feed prior to the harvesting of the 1940 crops but in some of the States the number of beef cattle is increasing.

COWS AND YOUNG STOCK ON JANUARY 1

Estimates of the inventory numbers of milk cows and heifers 2 years old or older on farms January 1 and estimates of heifers and heifer calves being saved for milk cows are shown on pages 8 and 9. These estimates show that during 1940 the number of milk cows increased in all except a few States. Comparison of the numbers of milk cows and young stock in the various parts of the country shows that the number of dairy heifers and calves is particularly large in relation to normal replacement requirements in the main producing section that extends from Minnesota eastward into Ohio. The number of calves is also large in some States where farmers are trying to build up herds that had to be greatly reduced during the droughts, and in some other States where dairy herds are being increased.

The inventory estimates of cows and heifers two years old or older kept for milk on farms January 1 should not be confused with the estimates of the average number of milk cows of producing age on farms during each year. The latter, shown on page 7, are used for estimating the annual production of milk in each State. While based on the inventory numbers at the beginning and end of each year they are lower because they exclude heifers that are two years old but not yet in production. They also differ slightly because of changes in numbers of cows during each year as a result of seasonal variations, changes in feed supplies and other factors.

MILK PRODUCTION PER COW FEBRUARY 1

Milk production per cow on Fabruary 1, as reported by crop correspondents was the highest on record for that date. Although also the highest on record a month earlier the reported production showed slightly more than the usual increase during January. On February 1, milk production was still above previous records for that season in all groups of States except the South Atlantic and South Central and even in those areas it was higher than in other years since the depression. For the country as a whole the February 1 production per cow reported by crop correspondents averaged 13.46 pounds this year compared with 12.65 pounds last year and a 1930-39 average of 12.29 pounds.

		The same of the sa	0				

The widespread tendency of farmers to increase the numbers of both dairy and beef cattle is now a factor of major importance to all who are trying to see what lies ahead for dairymen. Estimates of livestock on farms January 1 show 25,917,000 milk cows ("cows and heifers 2 years old and older kept for milk"). This is an increase of 2 percent over the number a year ago compared with a June 1939 to June 1940 increase of 1 percent. About 19.6 milk cows per 100 people are shown compared with 19.2 to 19.4 in the previous 4 Januarys and an average of 19.6 during the last 2 decades.

An unexpectedly large proportion of the calves on hand a year ago are being raised for dairy replacements and the number of heifers 1-2 years old, being kept for milk cows is estimated at 5,445,000. The number of calves now on hand is also large and it is estimated that in all about 5,929,000 heifer calves are now being raised for milk cows. These exceptionally large numbers of heifers and heifer calves indicate that further increases in milk cows may be expected in 1941 and 1942 unless drought or other unfavorable conditions cause drastic culling of dairy herds. The increase in all cattle during 1940 was 4.2 percent. The increases in milk cows and in all cattle are shared by practically all States.

The primary cause of these increases in both beef and dairy cattle is the high price of cattle compared with prices of other things and the large supplies of feed. As in other periods of rising cattle numbers the holding back of cows and heifers to increase the herds tends to reduce the number of cattle marketed and temporarily pushes the price of cattle higher than it would otherwise be. At times during 1940 the price of cattle was higher relative to the price of hogs and also higher relative to the price of hay than in any month during the previous 30 years. Good rains in the range States and the record supply of hay and roughage have also increased the demand for breeding stock. The price of milk cows, which largely determines the number of heifer calves raised for dairy purposes, appears low compared to the price of beef cattle but is still unusually high when compared with the value of the milk, grain, and hay required to raise a calf to milking age. As long as this situation continues dairymen will raise more than the usual proportion of their heifer calves.

Dairymen everywhere will be affected by the current and prospective increase in milk cows but the effects of the increases may be small compared with changes due to weather, pastures, war adjustments, and economic conditions. Other things being equal, a more rapid increase in the number of milk cows than in the population, as is the trend at present, tends to increase milk production per capita and tends to make price relations slightly less favorable for dairymen than would otherwise be expected. The less favorable returns normally result in a gradual shift towards less liberal feeding of concentrates to cows so that production per cow tends to decline after the number of cows per 100 people increases. The adjustment, however, never seems fully complete and it seems to lag half a year or more behind changes in the number of cows. On most dairy farms the adjustment will take the form of feeding a little more hay and less grain and maintaining or increasing production by milking an extra cow or two.

The price of milk cows is also affected by the increase in cattle numbers. The reduction in marketings is helping prices now but will mean increased marketings later on. As in 1917 and 1929, farmers are now able to sell aged cows at prices that are unusually high compared with the value of the feed utilized in raising the grown heifers on hand. This opportunity will disappear when normal culling of beef and dairy herds is resumed.
